

BIOS Modification for Clevo P870, P775 & P751

Enabling Upgraded NVIDIA GPUs to Use Official NVIDIA Drivers Without INF Modifications

I use generic BIOS that is provided from Clevo directly (latest one). It does not need to be modified more for the video card to work out of the box. It DOES however need to be modified if you want drivers to install automatically and without any issues (like Driver Signature Disabling etc).

AFAIK not Prema or dsanke BIOS will help you with that. My BIOS has that fixed (for P775TM1, P751TM1 only). However do not ask me here or in DM's to share my BIOS as I will not do that. I have done many modifications to it and spent lot of my time trying to make it work on lots of things not just the 3080. So I do not want to give it away just like that.

I would like to make a small tutorial on how to do it but for now I haven't found the time for it yet. It is actually not hard at all, all that is required to do is to extract a specific module from BIOS and change some values in the module to alter the Device ID in the BIOS. For those who are somewhat familiar with BIOS modding the module is called **BoardIDpei**.

This module is absent in P870xx BIOS'es and that's why the same modifications to make driver installations work without inf mods on P870xx does not work on P775/P751TM motherboards.

In the module you will find multiple references to **7708** or **0877** (sometimes in HEX in bios modules the ID's are written end first and beginning last or something) which correspond to default Device ID ending for P775TM1 and probably (just guessing) P751TM1 as they use same BIOS. This needs to be changed to **7715** or **1577** which corresponds to **X170KM-G** and after that you replace old BIOS module with new one. Flash new BIOS and you will see that drivers will install without any issues from GeForce website and GeForce experience. Automatic driver updates will work and basically it will be as it would be for X170KM-G. (Except dynamic boost and G-Sync)

If I remember correctly i just changed the ID in multiple places, it probably need to be changed only in one spot but as it worked, and nothing else was broken I never went back to check which one specifically was used for the GPU Device ID.

Hopefully this can help atleast someone who is somewhat familiar with modding to make it work for themselves. Maybe I will make a nicer tutorial in future but for now this is best I can say about it.

The tools I used for replacing and extracting the BIOS module was AMI Tools (more specifically **MMTool**) if you search on google UBU Tools it will have the additional BIOS Modding tools all in that package. If you are familiar with UEFI TOOL that probably can do the same trick too.

About heatsink I can't answer as I just bought custom from AliExpress and used that.

Good luck!
